TITLE:

A Method of Calculating the Equilibrium Between Liquid and Vapor in Three-component Systems II (Metod rascheta ravnovesiya mezhdu zhidkost'yu i parom v trekhkomponentnykh sistemakh. II)

PERIODICAL:

Zhurnal fizicheskoy khimii, 1959, Vol 33, Nr 6, pp 1353-1359 (USSR)

ABSTRACT:

On the basis of results obtained in a previous paper (Ref 13), a graphoanalytical method of calculating the equilibrium between liquid and vapor of three-component systems from data of binary systems was worked out. The method is based on the following: To the same extent as the third component is added to the binary system, the coefficient of relative volatility changes decreasingly with the change in relative concentration of the components forming the binary system, and tends to a terminal value $X_3 = 1$ for which γ_1/γ_2 is constant (γ_1 and $\gamma_2 =$ activity coefficients of the first and second components) and the maximum possible change of relative volatility of the first and second component (caused by the third component) is attained. By the data on the equilibrium of three binary

Card 1/3

A Method of Calculating the Equilibrium Between Liquid and Vapor in Three-component Systems II

sov/76-33-6-28/44

systems generated by the components of a ternary system, the position of the straight line can be determined which represents the activity coefficients of two arbitrary components as a composition (at a concentration of the function of the third component equal to zero or unity. By equation (1) (Ref 13), the function of the mean change in relative volatility on the concentration of the third component can be determined: $\lg(\gamma_1/\gamma_2)_{\text{mean}} = (Q_{13} - Q_{23}) / (1 - X_3)$. The change in relative volatility at any concentration of the third component can be regarded as a change which occurs at X3 = 1. The method is illustrated by the system acetonemethanol-water. To check the method of calculating, it was also applied to the systems butane-butene-furfurol, isobutanebutene-furfurol, methanol-carbon tetrachloride-benzene, benzene-cyclohexane-isopropanol, acetone-chloroformmethylisobutylketone, heptane-methanol-toluene, methylethylketone-heptane-toluene. A comparative table of the vapor compositions calculated by the described method, and determined by experiment, of the systems acetone-methanol-water,

USSR/Astronomy - Interstellar Matter

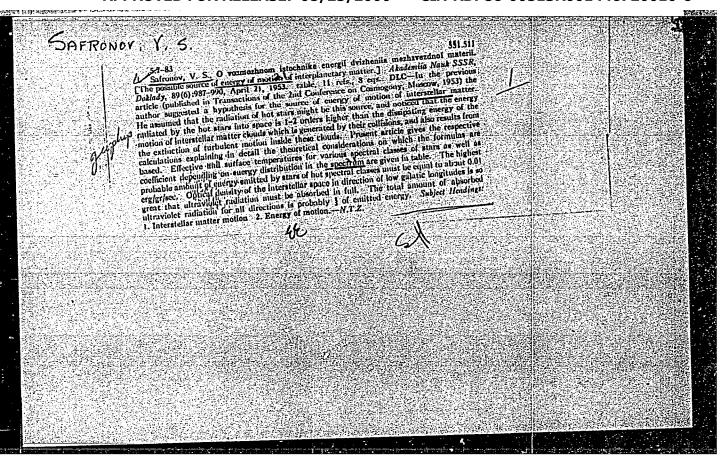

21 Apr 53

"Possible Source of Energy of Motion of Interstellar Matter," V. S. Safronov

DAN SSSR, Vol 89, No 6, pp 987-990

Concludes that subject motion results from: (*) transfer of gas and dust from high-pressure region to low; (b) action of direct pressure of light quanta on dust particles, neutral hydrogen atoms, and other elements (e. g., a cloud with 2.5-parsec radius, optical thickness tau = 0.3, mass 10 Suns, containing 1% dust particles and located 15 parsecs from type -08 star acquires by action of only pressure of light on the particles a velocity of 1 km/sec in 3 million years); (c) and, possibly, galactic rotation. Thanks S. B. Pikel'ner (of Crimean Astro Observatory). Presented by Acad O. Yu. Shmidt, 27 Feb 53.

Abstract

The regular plenum meeting of the Astronomic Council of the Academy of Sciences of the USSR, was held on Decem-ber 12-13, 1953 at Pulkovo, and was dedicated to the activity of the Council in 1953. On December 14-15, 1953 a conference on the coordination and planning of scientific research work in 1954 for all astronomical institutions in the USSR took place in Pulkovo. The fundamental

problems are: cosmogony, study of the sun, astrometry,

and celestial mechanics. Various committees made

their reports.

On a Turbulence Hypothesis in a Protoplanetary Cloud (O TITLE:

gipoteze turbulentnosti v protoplanetnom oblake)

PERIODICAL: V sb.: Vopr. kosmogonii. Vol 5. Moscow, AN SSSR, 1957, pp 22-46

In paragraph I the stability of a laminar rotational motion in a protoplanetary cloud relative to convection is investigated. A ABSTRACT: corresponding stability condition is deduced which in the case of moderate temperatures (heat velocities smaller than peripheral velocities) is reduced to the well-known convectiveinstability criterion

 $|dT/dn| > \gamma g/a_2R$

where a is a constant of the order of unity and g is the gravitational acceleration. This condition is known not to be fulfilled in a protoplanetary cloud as a result of which the erroneousness of Weizsäcker's cosmogonic hypothesis is deduced. If incipient

Card 1/2

SOV / 124-58-5-5548

On a Turbulence Hypothesis in a Protoplanetary Cloud

turbulence were present in a protoplanetary cloud, it would subside quickly. In paragraph 2 it is demonstrated that in a rotating turbulent protoplanetary cloud the tangential stresses depend on the gradient of the moment of the quantity of motion and not on the angular-velocity gradient as assumed by Weizsäcker, who had uncritically adapted the results obtained for the case of laminar motion to that of turbulent motion. It follows from the above that there is a tendency towards retention of the substance in the central part of the cloud and not a division of the substance into the outer portions moving away from the sun and the inner portions gravitating toward the sun, as was assumed by Weizsäcker. Paragraph 3 examines the process of the growth of the nuclei in the protoplanetary cloud. The growth of the nuclei does not prevent them from settling in the equatorial plane nor does it inhibit the increase in density to the critical point in the sense of gravitational instability. However, for this it is necessary for the relative velocities of the particles to be very small (of the order of 1cm/sec in the vicinity of the Earth and 100 cm/sec in the vicinity of large planets). Conference on the physics and the origin of planetary nebulae. (Saveshchaniye po fizike i proiskhozhdeniyu

planetarnykh tumannostey).

PERIODICAL: "Astronomicheskiy Zhurnal" (Journal of Astronomy),

1957, Vol.34, No.2, pp. 310-311 (USSR).

ABSTRACT:

This Conference took place on February 3-4, 1957, at the University of Leningrad. 75 persons took part. V. V. Sobolev gave a review paper on the contemporary

state of the physics of planetary nebulae. A. Ya. Kipper and V. M. Tiit gave a paper on

"Subdivision of light quanta and the relation of this

process to the physics of gaseous nebulae".

G. A. Gurzadyan devoted his paper to the dynamics of planetary nebulae. He noted that the most extended bipolar nebulae should be connected with the magnetic It is possible that bipolar structure is field. connected with the existence of a self-field of the nebula and different velocities of dispersion down and across the magnetic field. Gurzadyan considers that the planetary nebula is a remainder of a primary

material from which the central nucleus-star was formed. Gradual heating up of the star leads to a gradual expansion of the shell and its final separation.

Conference on the physics and the origin of planetary nebulae. (Cont.)

A communication on "Theory of ionisation waves of shells of stars, in connection with the problem of the origin of planetary nebulae" was given by S. A. Kaplan (cf. this issue p.183). S. B. I S. B. Pikel'ner and I. S. Shklovskiy discussed the nature of the spherical gaseous corona of the Galaxy. The authors criticised Spitzer's theory of the galactic corona.
They consider that the motion of the gas is sustained by the waves propagated from the centre of the Galaxy. I. N. Minin noted the great role played by light pressure in the nebula on the order of the HII region. I. S. Shklovskiy gave a brief version of his work on planetary nebulae published in issue No.3, 1956, of the Stronomicheskiy Zhurnal. B. A. Vorontsov-Vel'yaminov noted that in the majority of cases it is impossible to determine whether a given nebula is optically thin or optically thick. It follows that all scales of distances of planetary nebulae are subject to large systematic errors. P. P. Parenago pointed out that a good scale of distances of planetary nebulae does not as yet exist. Recd. Feb. 19, 1957.

Plenary session of the Astronomical Council of the Academy of Sciences of the USSR, devoted to reports and co-ordination. (Otchetno-koordinatsionnyy plenum astronomicheskogo Soveta Abademii Nauk SSSR)

"Astronomicheskiy Zhurmal" (Journal of Astronomy), 1957, Vol. 34, No. 3, pp. 503-504 (U.S.S.R.) PERIODICAL:

ABSTRACT: A plenary session of the Astronomical Council of the Academy of Sciences of the USSR took place on February 5-7, 1957, in Pulkov. It was devoted to reports on the activities of the Council in 1956, and the plans for research in the various astronomy departments in the USSR.

During 1956, the most active committees were those devded to the study of the sun and astrometry. Ten conferences were organised during 1956. A number of astronomers from abroad took part in these conferences. Soviet astronomers visited other countries and took part in the conferences there. Scientific contacts between Soviet astronomers and those of other countries were strengthened.

Prof. Kukarkin spoke on "International co-operation in astronomy". He pointed out that scientific contact and cooperation with astronomers abroad was of benefit to all. He suggested that while taking part in conferences abroad, Soviet card 1/2

On the Growth of Planets of the Earth's Group

PERIODICAL:

V sb.: Vopr. kosmogonii, Vol 6, Moscow, AS USSR, 1958, pp 63-77

(Engl. Res.)

ABSTRACT:

This is a discussion of the growth of planetary nuclei, caused by a simultaneous accumulation of small particles and larger bodies on their surface. Small particles are absorbed by larger bodies already in the early stage of their growth, if a crushing of the bodies does not occur. A cloud is changed to a "cluster", and the further process of nucleus growth consists in the accumulation of single bodies. The crushing of bodies during collisions prevents the complete absorption of particles by a cluster. A considerable part of the planetary matter must pass through repeated crushing and reunifications. The gaseous matter hardly participated in the growing process. The author takes into account the influence of the relative velocity of falling bodies on the earth's growth rate.

ABSTRACT:

The conference which was held from September 26 - 30,1957 in Baku was devoted to the scientific problems of the Azerbaydzhanian Astrophysical Observatory which is being built and to the preparation for the 700 anniversary of the observatory in Maraga. The new observatory is erected on the Pirkuli Hill in northwestern direction, 20 km from the Shemakha. The number of clear days and nights per annum amounts to 200-250. The best months are December and January. The project of the observatory is due to D.Kh. Yenikeyev and S.M. Vandov. At the moment there is only an astronomical observation station with a 200 mm meniscus telescope and a spectrograph on the Pirkuli Hill.

The observatory in Maraga was founded in 1259 by Mukhammed Nasireddin Tusi.

Reporting and Coordinating General Meeting of the Astronomical Council f the Academy of Sciences of the USSR from February 5 - 7, 1958 (Otchetno-koordinatsionnyy plenum astronomicheskogo soveta Akademii nauk SSSR 5 - 7 fevralya 1958 g)

PERIODICAL:

Astronomicheskiy zhurnal, 1958, Vol 35 Nr 3,pp 508-509 (USSR)

ABSTRACT:

February 5 - 7, 1958 there took place a general meeting of the Astronomical Assembly of the USSR in Pulkovo. Participaters: 1. Members of the Council 2. Head masters of the astronomical offices 3. The chairmen of the committees of the Council . The order of the day : 1. Report on the activity 1957 2. Coordination of the scientific activity of astronomical offices for 1958. A.A. Mikhaylov, Corresponding Member of the Academy of Sciences and Chairman of the Astronomical Council poke about point 1. It was emphasized: The very intensive activity because of the sputnik experiments, the contact with foreign countries in observations of sputniks, agreement with Czecho-Slovakia, Roumania, Hungary, Jugoslavia, China and Mongolia on the performance of common observations of the sun. The astronomical meetings which took place in the USSR in 1957 and the international meetings visited by Soviet

Astronomical council f the Academy of Sciences of the USSR from February 5 - 7, 1958

astronomers in 1957 were enumerated. Concerning point 2 it is mentioned that an intensification of the construction of astronomical instruments is commended to be urgently necessary. On February 7 A.G. Masevich spoke about the astronomical observations of the sputniks which were carried by 70 stations in the USSR. In the astronomical council, a team under the guidance of A.M. Lozinskiy elaborates the theory of method of the visual and photographic sputnik observations.

SOV/49-59-1-16/23 Safronov, V. S. AUTHOR:

On the Initial Temperature of the Earth TITLE: (O pervonachal'noy temperature Zemli)

PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Geofizicheskaya,

1959, Nr 1, pp 139-143 (USSR)

There are two main hypotheses on the origin of the ABSTRACT: Earth. One of them, developed by Shmidt (Ref 1), Edgeworth (Ref 2). Gurevich and Lebedinskiy (Ref 3), suggests that the Earth was formed by accretion of

solid particles and small bodies. On this hypothesis the Earth was initially relatively cold. On the other hypothesis (Fesenkov, Ref 4) the Earth was formed from

a very massive cloud consisting of gases of interstellar dust. From a portion of such a cloud protoplanets were formed. These protoplanets

contracted rapidly, lost their light gases and were transformed into very hot planets. The protoplanetary hypothesis meets, on closer analysis, with serious difficulties. It is difficult to see how the original

protocloud, and the protoplanetary cluster formed from Card 1/3

On the Initial Temperature of the Earth SOV/49-59-1-16/23

it, lost eventually most of their mass. The chemical composition of the Earth also contradicts the protoplanetary hypothesis, but it can be explained on the basis of the cold accretion hypothesis, as shown by Urey (Ref 9). The accretion hypothesis suggests that the Earth grew by attraction to its nucleus of solid particles and bodies from the protoplanetary cloud. The initial temperature of the Earth, i.e. the temperature at the end of the formation process, would be due to:

1) heating due to impact of the attracted particles and

2) radio-active heating of the growing nucleus,
3) heating of this nucleus by gradual compression due

to the growing outer layers.
The author considers these three mechanisms of temperature rise and reviews the work already reported. He concludes that at the end of its formative period, estimated at 10⁸ years, the temperature of the Earth's centre was about 1000 K. The heat came mainly from decay of radio-active elements and compression during

Card 2/3

On the Initial Temperature of the Earth

SOV/49-59-1-16/23

growth of the initial nucleus. Heating by impact of the attracted bodies made only a small contribution. Further heating of the Earth occurred again by radioactive decay. The radio-active content of the Earth could raise the temperature of the Earth's core by several thousand degrees in a period of 5 x 10 years. Such radio-active heating is important in all considerations of formation of the Earth and especially of its crust.

TITLE:

Accumulation of terrestrial planets

PERIODICAL:

Voprosy komogonii, v. 7, 1960, 59-65

TEXT: A quantitative investigation has been made of the process of accumulation. The very first state of the cloud of matter is assumed to have been sunlike and to have been followed by a separation into gas and dust, with the solid matter accumulating in the cloud's equatorial plane. Gravitational conditions have been thoroughly discussed by L. E. Gurevich and A. I. Lebedinsky (Izv. AN SSSR, Ser. Fiz., Vol. 14, p. 765, 1950). To attain Roche's density in the dust layer it is necessary for the velocity of the particles to not exceed a certain critical value. In an early stage of the cloud's evolution, a swarm of bodies probably rotated to an ever-increasing density, whereby also the gravitational interactions were intensified. The gaseous matter, however, was not essentially involved in the process of accumulation. In previous studies already, the author has been dealing with the problem of the accumulative growth of planetary embryos. Papers by

Card 1/4

Ę,

s/555/60/007/000/003/007 B123/B201

Accumulation of terrestrial planets

O. Yu. Shmidt are also available on this subject (Dokl. AN SSSR, Vol. 46; p. 392, 1945). The growth rate of a planetary embryo of mass m has been found to be expressed by $\frac{dm}{dt} = \gamma \pi r_e^2 qv = \frac{4\pi y}{P} r_e^2 \sigma(t) \quad r_e = \text{effective radius of the planetary embryo},$

 $\frac{dm}{dt} = \gamma \pi r_e^2 cv = \frac{4\pi \gamma}{P} r_e^2 \sigma(t) \quad r_e = \text{effective radius of the planetary embryon}$ $\gamma = \text{probability of association in collisions, and } P = \text{time of revolution}$ about the sun.

 $\sigma(t) = \sigma_0 \left(1 - \frac{m}{Q}\right)$, where Q denotes the present mass of the planets; $v = \sqrt{G_m/2r}$, where the factors leading to a decrease of velocity are not taken into account. Results of calculations are given in the present periodical, Vol. 6, p. 63, 1958. Calculations made by Ye. A. Lyubimova (Izv. AN SSSR, Ser. Geofiz. No. 5, p. 416, 1955) are also reported; the temperature at the end of the growth of the Earth attained a maximum at the center - during 108 years it increased to 1000° K. Also the heating of the Jupiter surface is discussed; it probably exceeded 1000° K. This permits explaining the higher density of the inner Jupiter satellite. The problem regarding the disintegration of smaller bodies in collisions is also discussed. It is possible

Card 2/4

s/555/60/007/000/003/007 B123/B201

Accumulation of terrestrial planets

Card 3/4

to distinguish two stages in the evolution of the swarm: in masses of the order of $10^{22}g$ disintegration, and over $10^{26}g$ evaporation with consequent condensation. If β is the probability of disintegration in the case of one collision, and $(1-\beta)$ the corresponding probability of association, then, on a growth of the mass of the body from m to m, the portion p of the total mass which has undergone disintegration will be $p\approx 1-(m_0/m)^{\beta}$. If, e.g., $\beta=0.1$, $m_0\approx 10^{22}g$, and $m_0/m=10^{-2}$, then $p\approx 0.7$. Detailed studies of chemical interactions have been conducted by A. A. Yavnel' (Astr. Zhurn. Vol. 34, p. 445, 1957). Valuable data can be also obtained from an analysis of planetary rotation. A body hitting a growing planet of mass m and radius r causes an increase of the moment of momentum of this planet by $\Delta K = \alpha r v \Delta m$, where Δm , v, and αr denote the mass, velocity, and distance from target of the hitting body. The mean value α is small, but still different from zero, and consists of two components, one systematic and the other accidental. The latter component manifests itself in the inclination of the planetary equator to its orbital plane, while the systematic one shows in the planetary rotation. The growth process of the larger planets is complicated by the following factors: dissipation of matter from this zone, accretion of

the gas by the more massive embryonal planets, the possible transition of

Accumulation of terrestrial planets

3/555/60/007/000/003/007 B123/B201

part of the hydrogen into the solid state. A study of these problems is necessary for a quantitative examination of the process of accumulation of the larger planets. There are 14 references: 9 Soviet-bloc and 5 non-Soviet-bloc.

On the Cravitational Instability in Plane Rotating Systems

With Axial Symmetry

PERIODICAL:

Doklady Akademii nauk SSSR, 1960, Vol 130, Nr 1, pp 53-56 (USSR)

ABSTRACT:

K.F. Ogorodnikov (Ref 3) underlined the physical irreality of systems which are infinitely expanded in the direction of the axis of rotation. It is the aim of the present paper to determine the critical density for a real plane rotating cloud. Like the authors of earlier papers, Safronov assumed that the cloud maintains its axial symmetry during the entire period and that therefore the disturbances are radial (ring-shaped).

The condition $4\pi G_Q > \frac{2\omega}{r} (\omega r^2)' + \frac{4\pi^2 c^2}{\lambda^2} + \frac{c^2}{4r^2}$ characterizes

the equilibrium of the forces acting on that element which has shifted through the disturbing wave in the radial direction by $\delta r = 1$ without change of the angular momentum with respect to the center of mass of the system. In transition from the system which is infinite with respect to z to finite systems only the term related to gravitation changes in the above

Card 1/3

507/20-130-1-14/69

On the Gravitational Instability in Plane Rotating Systems With Axial Symmetry

inequality. In this case Poisson's equation does no longer hold, and it is more convenient to calculate 5F, directly.

The following expression is then obtained:

 $\int_{0}^{\pi} \frac{\int \rho(\operatorname{rccs}\psi - r_{0}) \operatorname{rdrdhd}\varphi}{(r^{2} + r_{0}^{2} + h^{2} - 2\operatorname{rr}_{0}\operatorname{cos}\varphi)^{3/2}}$

Here, r denotes the distance from the axis of rotation, h the distance from the central plane of the cloud. Integration of this expression leads to elliptical integrals the evaluation of which is discussed step by step. The expression

 $4\pi G_Q f(\frac{\xi}{\xi}) > \frac{2\omega}{r} (\omega r^2)' + \frac{4\pi^2 c^2}{\sqrt{2}}$ is found for the condition of the gravitation-dependent instability the function f(f)

assuming the following values: 2 4 6 8 10 f(:)0.96 0.64 0.43 0.34 0.28 0.23 0.172 0.124 The correction for the critical density is therefore considerable and depends on the ratio between the wavelength of the

Card 2/3

On the Gravitational Instability in Plane SOV/20-130-1-14/59 Rotating Systems With Axial Symmetry

disturbance and the density of the layer. The author then determines the value of for which the density necessary for the gravitation-dependent instability is very small. For this purpose a formula derived by Ye.L.Ruskol (Ref 6) is used. The critical density necessary for the gravitation-dependent instability is very small if the wavelength of the disturbance is eight times higher than the density of the cloud. The minimum value of the critical density c = 2.1 is more than six times higher than the value determined by N.Bel and E. Schatzmann. Thus, the conditions found here for the gravitation-dependent instability in the interstellar matter of the Gravy are assumed more rigorously than has hitherto been done. There are 6 references, 3 of which are Soviet.

wavelength and the scattering of light by the particles is taken to be isotropic. The homogeneous half-thickness of the layer is assumed to be proportional to the distance from the Sun (h = βR). The linear dimensions of the Sun in the z direction are taken into account. The problem is divided into two parts, namely, determination of the temperature inside the dust layer for a given boundary temperature and determination of the boundary temperature itself. A table is reproduced giving the temperature of the layer for different values of and it is shown that the temperature increases .. with β . The maximum heating of the layer is due to light scattered by the gas component of the cloud. The temperature of a black body inside the layer is found to be of the order of 30 - 35 K at a distance corresponding to the distance of Jupiter from the Sun, while at a distance of Saturn the result is 15 - 18 °K. It is concluded that the condensation

Card 2/3

On the temperature

5/033/62/039/002/007/014 E032/E314

of hydrogen on particles inside the layer is impossible at distances corresponding to those of Jupiter, Saturn and Uranus. Condensation of hydrogen at the distance of Neptune is considered to be unlikely. There are 2 tables.

Special case of the solution to...

where (11) takes on the form

$$\frac{1}{A_1 \varphi(t)} \frac{\partial g}{\partial t} = \frac{m}{2} \int_0^m g(m-m',t) g(m',t) dm'. \tag{6}$$

In addition, the variable

$$d\tau = MA_1 \varphi(t) dt, \qquad \tau = 1 - e^{-A_1 M t}. \tag{7}$$

is introduced. Use of the Laplace transform

$$G(p,\tau) = \int_{0}^{\infty} e^{-pm} g(m,\tau) dm \qquad (8)$$

gives the quasilinear equation

$$M\frac{\partial G}{\partial \tau} + G\frac{\partial G}{\partial \rho} = 0. \tag{9}$$

The solution is

$$G(p,\tau) = \int_{0}^{\infty} e^{-(Mp-\tau G(p,\tau)+N_0)m/M} n(m,0) dm.$$
 (11).

Card 3/5

S/020/62/147/001/009/022 B104/B102

Special case of the solution to ...

Only in a few cases can $G(p,\tau)$ be given explicitly. With an initial distribution $n(m,0) = am^{-q}exp(-bm)$ the author considers only the case q=0, i.e. the initial distribution

$$n(m,0)=ae^{-bm}, \qquad (14)$$

$$a = N_0^2/M = N_0/m_0, \quad b = N_0/M = 1/m_0,$$
 (15)

which has the solution

$$G(p,\tau) = \frac{M}{2\tau} \left[p + 2b - \sqrt{(p+2b)^2 - 4b^2\tau} \right]. \tag{18}$$

This solution gives the mass distribution functions

$$n (m, \tau) dm \approx N_0 (1 - \tau) e^{-(1+\tau) m/m_0} \frac{dm}{m_0}$$
 (23)

for 2m/t≪m and

$$n(m, \tau) dm \approx \frac{N_0(1-\tau)}{2\sqrt{\pi}\tau'^{l_1}} \left(\frac{m}{m_0}\right)^{-s/s} e^{-(1-\sqrt{\tau})^s m/m_0} \frac{dm}{m_0}$$
 (24)

Card 4/5

Special case of the solution to...

5/020/62/147/001/009/022 B104/B102

for $2m\sqrt{\tau}\gg m_0$. m_0 is the mean initial mass of the bodies. (24) can be used for the largest range of values of m and τ . At this stage the large bodies make up much of the mass in the system, and the relative mass of the large bodies increases with time. Furthermore it is concluded that at the last stage in the evolution of the earth the major part of the mass consisted of large bodies.

TIME: History of lunar atmosphere and the probability of occurrence of ice and organic compounds on the moon

SOURCE: Astronautyka, no. 1, 1963, 1-4

TOPIC TAGS: lunar atmosphere; 0; CO; N sub 2; H sub 2; meteoric impact; vapor traps

ARSTRACT: In connection with the planned exploration of the moon's surface it became necessary to know whether various volatile substances and vapors liberated from the moon's surface may be retained as frozen substances on that part of the moon's surface which is not exposed to solar radiation. This problem is connected with the origin of the moon. It is assumed that the original lunar atmosphere consisted mostly of water vapors and CO sub 2. During the many years of

Card 1/2

ACCESSION NR: AP3000265

the moon's formation, perhaps as many as 3 billion years, practically the entire atmosphere disappeared into space, and the moon's interior became practically degasified. Using Jeans's reasoning, the authors determine how far the lunar atmosphere extends, and construct a model of this atmosphere giving its limits, probable density escape and speed of dissipation. In a table the probable composition and density of the lunar atmosphere are given at temperatures of 400, 600, and 1,000K. There are probably traps, formed during the past million years, where certain amounts of gases have been retained and frozen. These traps are very small, and ice evaporates from them very slowly. Meteoric impacts may probably liberate some frozen water vapors. [Abstracter's note: As presented in the cited source, this art. is actually a condensed abstract (prepared by Andrzej Marks) of the orig. art. by Safronov and Rouskol. There is no indication where the orig. art. appeared.] Art. contains 1 table, 7 equations.

gony), v. 9, 1963, 188-195

TOPIC TAGS: astronomy, astrophysics, Metagalaxy, gravitational instability, protoplanetary cloud, cosmology, Galaxy, magnetic field, gas nebula, universe

ABSTRACT: The theory of gravitational instability as applied to rotating systems, the Galaxy and a protoplanetary cloud, is discussed. It is argued that the expansion of the Metagalaxy originates not from a point, but from a region of finite dimensions with finite density. The contributions made by Jeans, Gurevich, Lebedinskiy, Chandrasekhar, Bel, Schatzman and Safronov to the solution of this problem are reviewed. The author contends that application of the theory of gravitational instability to the Galaxy as a whole has shown that individual stars could not be formed by this process. Gravitational instability can lead to the formation of considerably larger condensations with a cross section of the order of the width of spiral arms. The actual picture is complicated by many factors,

CIA-RDP86-00513R001446720010-6" APPROVED FOR RELEASE: 08/25/2000

ACCESSION NK: AT4019692

of which magnetic fields are one of the most important. The idea of formation of stars in groups, illustrated by the case of stellar associations, is in full agreement with the conclusions which can be drawn on the basis of the concepts of gravitational instability in the Galaxy. The application of the gravitational instability theory to a cloud rotating around the sun has shown that the critical density could not be attained in the gas component of the cloud, but it could develop in the dust component. This could lead to the formation of a large number of dust condensations with masses of the order of 10-7-10-10 planetary masses. The Jeans theory of gravitational instability in an infinite homogeneous medium encounters difficulties which do not appear when instability is considered in real rotating systems of finite dimensions. The importance of the rotation factor in cosmology is stressed, since this factor is often neglected in cosmological models. The paucity of knowledge concerning the past and future of the Metagalaxy is discussed. The author considers the concept of the compression (or expansion) of the entire infinite universe toward a single center, and the rotation of an infinite universe as a single entity to be quite artificial; it would be more correct to speak of compression and rotation of finite parts of the universe. It is shown that models: with a maximum density substantially less than nuclear and with a state of matter determined by their prehistory merit attention, especially those involving collisions and destruction of a considerable number of stars, making it improbable that the expansion of the universe was completely uniform and isotropic. TITLE: History of the lunar atmosphere and the pessibility of existence of ice and organic compounds on the moon

SOURCE: AN SSSR. Astronomicheskiy sovet. Voprosy* kesmegenii (Preblems of cesmogony), v. 9, 1963, 203-214

TOPIC TAGS: astronomy, moon, lunar atmosphere, lunar ice, lunar radioactivity, lunar interior, lunar surface, lunar evolution, lunar crater

ABSTRACT: The maximum density and probable composition of the ancient lunar atmosphere are considered. It is assumed that the moon was formed as a cold solid mosphere are considered. It is assumed that the moon was formed as a cold solid body, with a relative abundance of volatile substances similar to that of the earth. The total quantity of released volatiles is placed at 100 kg H2O, 5 kg cold and 0.23 kg N2 per square centimeter of the lunar surface. On the basis of cold and on the thermal history of the moon, heated by radioactive elements, it is postulated that the period of intense degassing of its interior coincided with the period of its melting (about 2.5-3.109 years ago) and lasted about 109 years. During the accumulation of the atmosphere its escape rate increased and when the degassing attenuated atmospheric density decreased to its present value. The

AT4019694 ACCESSION NR:

maximum density near the surface is determined from the equality of the escaping flux to the flux from the interior during the period of active degassing and is found to equal 10-8 to 10-9 of that of the present-day terrestrial atmosphere. This corresponds to a density at heights of about 150 km above the earth's surface: The most abundant components of the lunar atmosphere, H2O and CO2, therefore were dissociated mainly into 0 and CO. Liquid water probably never existed on the lunar surface because the density of water vapor was always much lower than saturation density. The presence of methane in the lunar atmosphere probably was impossible because methane is unstable in the presence of free oxygen. The authors disagree with the conclusions drawn by Watson, Murray and Brown that permanently shaded craters in the polar regions or "cold traps" were of great importance in the process of redistribution and convervation of RgO on the moon of on their role as indicators of ancient activity of the lunar interior. The volume of these "traps" would permit lunar retention of not more than 10-3 of the total amount of released water. The suggestions made by C. Sagan also must be revised. Sagan concluded that certain complex erganic compounds of the amino acid type can exist in the lunar soil in considerable quantity. His statement is based on the assumption that in the past the moon had a very dense atmosphere containing methane, ammonia and other gases in which erganic synthesis was pos-The rarefaction of the lunar atmosphere, the predeminance of photodissesible. 2/3

SOURCE: AN SSSR. Izvestiya. Fiziki zemli, no. 7, 1965, 1-8

TOPIC TAGS: earth crust, geophysics

ABSTRACT: A study of the process of accumulation of the earth from solid bodies and particles by methods of the theory of coagulation leads to the conclusion that a significant part of the mass of accumulated substance was concentrated in large bodies: Large bodies falling on the earth with randomly oriented velocities caused deviation from "direct rotation." From the angle of inclination of the equator to the ecliptic, it is found that the mass of the largest bodies which have fallen on the earth were on the order of 1/1,000 the mass of the earth, i.e., about 1,000 kilometers in diameter. Small differences in density and composition of the large bodies could lead to appreciable inhomogeneities in the earth's mantle. The falling of bodies with diameters of hundreds of kilometers was accompanied by heating of
